

Random ensembles live at $r = 1$; designed families do not.

The designed 'backdoor' generator is drawn apart — pooling it would read 65.3%, not 79.6%

five random generators — $n = 1914$ of 2400 rows; excluded: 486 rejected at generation

designed 'backdoor' generator — $n = 420$ of 480 rows; excluded: 60 generator error

designed census family — $n = 1572$ of 1584 rows; excluded: 12 rejected at generation

12 designed 'backdoor' rows carry an UNREACHED (-1) GAC radius; their back-door radius is exact and is the one plotted
