

Supplementary: mean S(d) per depth, by bucket (flip arm) — noise-dominated at high d

Supplementary per-depth view: mean S(d) by bucket, flip arm, $n_{\text{eval}} \geq 30$ cells only; marker area $\propto \sqrt{\text{contributing instances}}$; a line breaks wherever the next depth lacks such a cell (never bridged). n thins fast with depth, so this view is noise-dominated at high d — both panels show real crossings among the middle buckets past $d \approx 3$ -4. shd_truth = 0 also includes every coverage=1.0/base-wrongness=0 instance, where it is $\equiv 0$ by construction — a separate reason it cannot rank, not merely tangling. r_val carries Conjecture 2 (hence Anti-Exchange Case B, verified not proved); the error is one-sided, so radii can only be too large. See F1 for the endpoint (AUC_frac) and F3 for the rank-correlation test — the primary evidence for P1/P2.
